1

How things behave in small scale?

- E.g. Ants vs. Human

| | |
|---------------------------------|------------------|
| Lift 10 times of its own weight | (Barely 1 times) |
| Do not injure when falling | (easily injured) |
| Some can fly | (we wish) |
| (Dead near fire) | We cook |
| (Dry cleaning) | We take showers |
| (? If they are smart?) | We use tools |

3

Problem of Direct Scaling

- We don't have a good intuition of microscale physics. Our common sense in the macro-world often get flawed in the microworld
- What shall we do?
 - Dimensional analysis could reveal “How things behave” in the microscopic world without full scale analysis.
 - In fact, you might have exercised these in many thermal/fluidic problems!

5

Scaling Physics

- Most physical quantities (force, torque, power, etc) scales differently with dimension L

- Assuming geometric similarity
 - Surface force $\propto L$ (size)
 - Heat transfer, Diffusion $\propto L^2$ (area)
 - compression/elongation stiffness $\propto L^2$ (area)
 - Mass $\propto L^3$ (volume)

ME 498

6

Why dimensional analysis?

- Intuition tends to perceive the micro/nanoscale objects as geometrically similar counterparts of those in macroworld
→ hinders conceptual level designs
- As scale reduces, some physical quantities become dominant while others become negligible

7

Classical Mechanical Scaling Laws

| Quantity | Scaling Law |
|---------------------|-------------|
| Acceleration | L^{-1} |
| Energy density | L^0 |
| Characteristic time | L |
| Friction force | L^2 |
| Mechanical power | L^2 |
| Torque | L^3 |
| Energy/work | L^3 |

8

Standing

- The diameter of a tall tree must increase as $3/2$ of its height ($L^{3/2}$)
- Young and small trees appear slender, and old and tall ones appear squat or stunted

Also applies to weight lifting and even to production of nails

ME 498

9

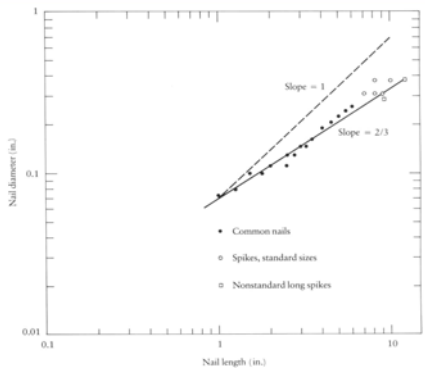

Scaling of Nails

Common nails arranged by size from 60 penny (6 inches) to 2 penny (1 inch).

Nail diameter vs. nail length on a log-log plot, showing the allometric formula $d = 0.07L^{2/3}$. A broken line of slope 1.0, representing strict isometry, is also shown.

10

Jump Height Record

Jumping:

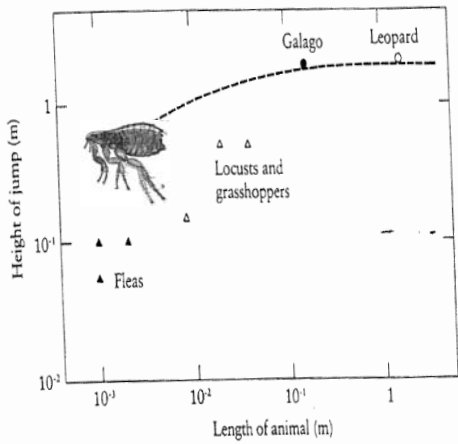

- The work done in leaping up is proportional to the mass and height of the jump

$$W/M \sim gh$$

- Power density is almost invariant with size in different animals:

$$W/ M \sim L^0$$

- Thus h tends to be constant irrespective of the animal

11

Flying and Rotating

- Flying (birds fly from 10.8 to 20.7 m/sec):
 - Wing length $\sim l \sim M^{1/3}$ and wing area $\sim l^2 \sim M^{2/3}$
 - The characteristic speed for flying varies as $l^{1/2}$ or $M^{0.17}$
 - Drag/lift forces are given by $L = 1/2 C_L \rho A v^2$. This expression has an order of $2 + 2v$
 - Of key importance is the lift-to weight ratio (divide by l^3) which is of the order $2v^{-1}$
 - Since the lift-to-weight ratio should be invariant with scale to achieve flight a zero order scaling law is needed thus v must be $1/2$ to achieve sufficient lift (same result as above)
- Rotation:
 - Mass moment of inertia (I) = $\int r^2 dm$. This is a fifth order expression
 - A small motor will reach top speed in a fraction of a second, large motors may require seconds to reach full speed

12

Relative Significance of Forces

e.g. Absolute deflection of a beam (width H , length L) due to its own weight

$$\delta = \frac{3}{2} \frac{\rho g}{E} \left(\frac{L}{H} \right)^2 L^2$$

Percent deflection (Keep L/H the same)

$$\frac{\delta}{L} = \frac{3}{2} \frac{\rho g}{E} \left(\frac{L}{H} \right)^2 L \propto L$$

The relative deformation of 2 μm long beam would be 1/1000 of the 2mm beam!

- In microscale, structures appear to be stiffer against inertia forces

13

Surface Force

- Adhesion, surface tension

A thermodynamic property

- $dG = \gamma dA$
- Unit : J/m^2 or N/m

ME 498

16

Pressure in Small Bubbles/Droplets

Laplace-Young Equation relates the pressure drop to the surface tension and the dimension of the bubble/droplets:

$$\Delta P = \frac{2\gamma}{r} \quad \text{droplets}$$

$$\Delta P = \frac{4\gamma}{r} \quad \text{bubbles}$$

The relative pressure inside a 50nm vesicle could exceed 400kPa (~4 atm)!

17

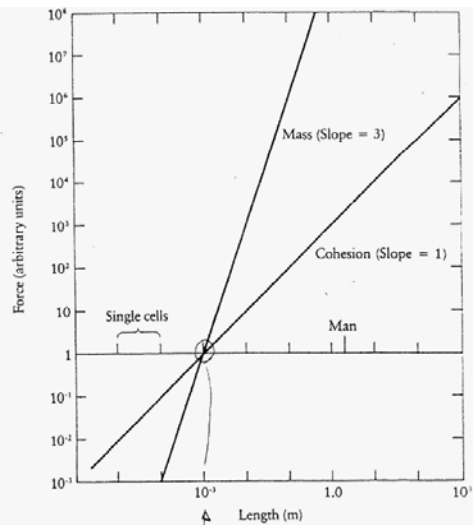

Body Force vs. Surface Force

A water strider floating on a pond without worrying gravity

Bond Number

$$Bo = \frac{\text{gravity}}{\text{viscous}} = \frac{\rho g L^3}{\gamma \mathcal{L}} = \frac{\rho g L^2}{\gamma}$$

18

Quiz: a bridge for cells

Assuming we need to construct a $1\ \mu\text{m}$ thick silicon bridge for the cells to travel between two of their villages, $500\ \mu\text{m}$ apart, on top of a drop of water between the two villages. We want to construct a strong bridge that would not collapse easily. Which type of bridge among the followings is the most suitable?

(A) Beam bridge,
aspect ratio ≈ 10

(B) Truss bridge,
aspect ratio ≈ 100

(C) Suspended bridge,
aspect ratio > 100

19

Scaling in Fluidics

Reynolds Number:

$$\text{Re} = \frac{\rho \frac{U^2}{L} \quad (\text{inertia})}{\mu \frac{U}{L^2} \quad (\text{viscous})} = \frac{\rho UL}{\mu}$$

In typical cases of
micro/nanofluidics

$$\rho = 1\text{g} / \text{cm}^3, L = 10^{-6}\text{m}$$

$$U = 0.01\text{m} / \text{s}, \mu = 10^{-3}\text{Pa}\cdot\text{s}$$

$$\text{Re} = 0.01$$

The flow is highly laminar!

20

Consequence of Microfluidics

Incredibly High Flow Resistance $R = \frac{8\mu L}{\pi r^4} \propto L^{-3}$

Viscous Drag $C_d \sim 1/Re$

Poor Mixing

No turbulent mixing
Slow diffusion at L-L interface only

Branebjerg *et al.* *MicroTAS Proceedings*, 141 (1995)

ME 498 © 2006-08 Nick Fang, University of Illinois. All rights reserved. 21

Stopping Distance at Low Re

- Can a Fly Catch a fish like Pelican?
- A viscous drag would prevent that!

$$(3\pi\mu Dv)l = \frac{1}{6}(\rho - \rho_0)\pi D^3 v^2$$

- Stopping Distance $\sim (Re/18)D$

A fly could only dive in a few centimeters;
A cell would only slide at a fraction of the diameter (<1um)

ME 498 © 2006-08 Nick Fang, University of Illinois. All rights reserved. 22

Swimming in Low Re Flow

- It's much like swimming in a slurry
 - Your body move forward on the thrust stroke **but** go backward at equal distance at return stroke: effect of **reversibility**

Without diffusion, a vesicle released by the cell would be taken back by an reverse motion of the membrane!

24

Thermal scaling (Classical)

- Heat capacity $\sim L^3$
 - assuming that the specific heat capacity is to remain constant
- Heat dissipation (by conduction, convection and radiation) $\sim L^2$
- **Biot Number** representing the heat resistance:

$$B = \frac{hL}{\kappa}$$

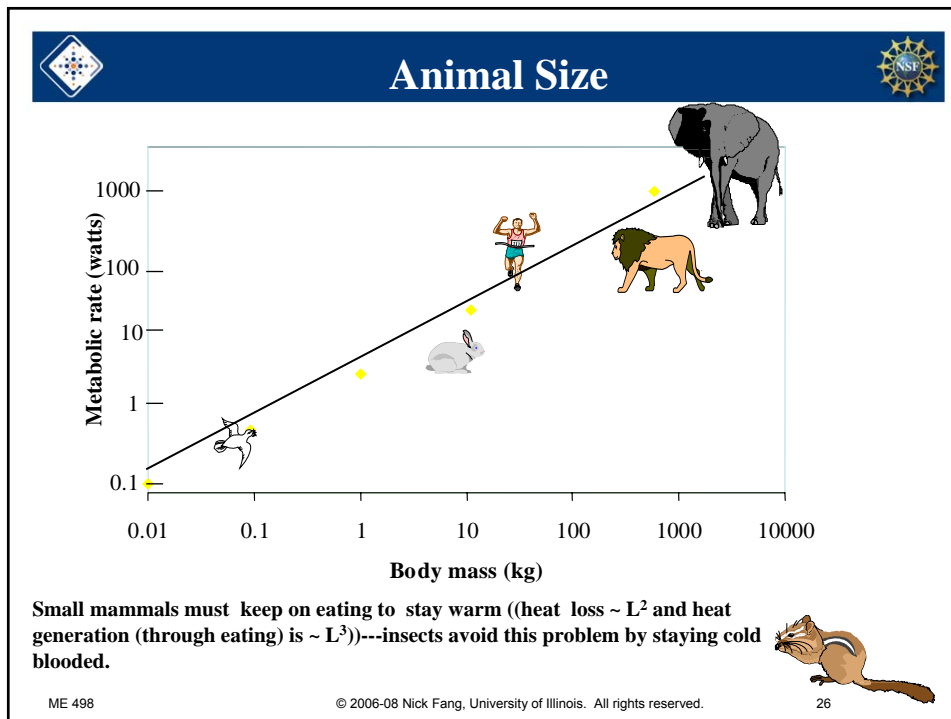

This implies that micro/nanoscale object can be heated faster and cooled faster

- **Peclet Number** showing the ratio between convection to conduction:

$$Pe = \frac{\rho C_p vL}{\kappa}$$

This implies that convective heat transfer become negligible compared to conduction

25

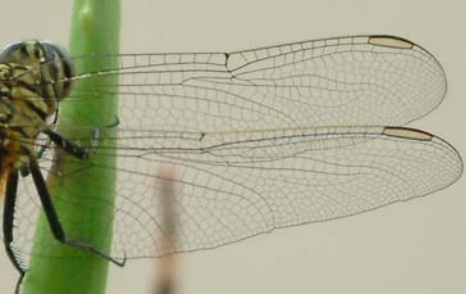

Another note on mass transport

- Dragonfly uses air filled tubes instead of blood to transport oxygen to muscles

ME 498 © 2006-08 Nick Fang, University of Illinois. All rights reserved. 28

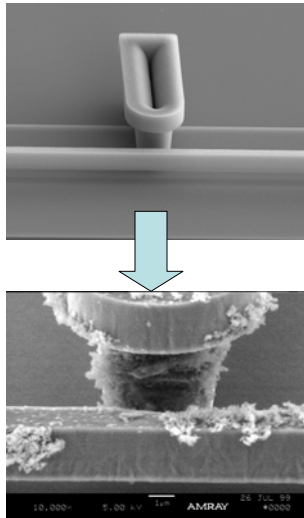

Classical Wear Life

- Unlubricated system
 - Constant interfacial stress
 - Constant speed
 - Erosion rate = constant
- Wear life \propto thickness/erosion rate $\propto L$
- 1-cm part \rightarrow 10 years
1-nm part \rightarrow 30 seconds !

Fortunately, that never happened

Michael T. Dugger, Sandia National Lab

29

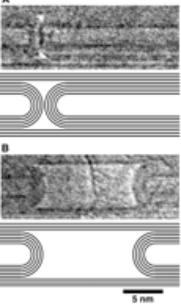

Nanoscale Friction

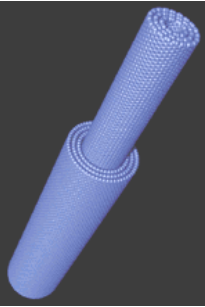

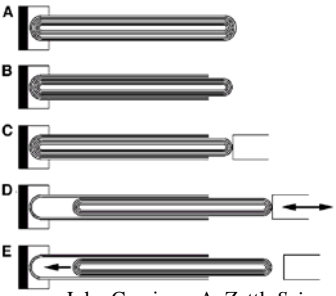

20 nm

- Telescoping nanotube segments
- No wear or fatigue
- van der Waals energy-based retraction force

5 nm

30

Breakdown of Continuum Theory

- Because of non-linear effects electrostatic devices can be operated in air without breaking down (operation on the left side of the Paschen curve).
- New physics and chemistries to be explored.
