Part III (Free Response, 30 points)

Consider an ideal silicon *pn*p BJT at room temperature. The doping concentrations at emitter, base and collector are respectively  $N_{A,E} = 10^{17} \text{ cm}^{-3}$ ,  $N_{D,B} = 10^{15} \text{ cm}^{-3}$ , and  $N_{A,C} = 10^{14} \text{ cm}^{-3}$ . The base width is  $W_B$ . Assume that the minority carrier diffusion lengths  $L_{n,E} = 40 W_B$ ,  $L_{p,B} = 5 W_B$ , and  $L_{n,C} = 200 W_B$ . The total and quasi-neutral base widths depicted below are schematic, and may not be to scale.

- a. Write an expression for the quasi-neutral base width  $W'_B$  as a function of  $W_B$ ,  $V_{EB}$ , &  $V_{CB}$ . You may use the one-sided junction approximation.

- b. Sketch the excess minority carrier concentration across the emitter, base, and collector quasi-neutral regions, if  $V_{EB}=0.5$  V and  $V_{CB}=0.3$  V. Please indicate any assumptions about the emitter and collector thicknesses. What is the operating regime of the BJT under this condition?

- c. Given that the emitter injection efficiency  $\gamma_F$  is 0.99, find the emitter current gain  $\beta_{dc}$ . Assume that  $W'_B = 0.8 W_B$  in this operating condition.
