quantum vs. semi-classical transport

particle or wave?

\[ p = \hbar k = \hbar \frac{2\pi}{\lambda_B} \]

\[ E = \frac{p^2}{2m^*} \approx \frac{3}{2} k_B T \]

\[ \lambda_B = \sqrt{\frac{4\pi^2 \hbar^2}{3m^* k_B T}} \approx 10\text{nm} \text{ (electrons in Si at 300K)} \]
semi-classical transport

\[ E(x,k) = E_C(x) + E(k) \]
semi-classical transport

\[ E_{TOT} = E_C(x) + E(k) = \text{constant} \]
semi-classical transport

\[ E_{TOT} = E_C(x) + E(k) \]

\[ \frac{dE_{TOT}(x,k)}{dt} = 0 = \frac{dE_C(x)}{dx} \frac{dx}{dt} + \frac{dE(k)}{dk_x} \frac{dk_x}{dt} \]

\[ 0 = \frac{dE_C(x)}{dx} v_x + \frac{1}{\hbar} \frac{dE}{dk_x} \frac{d(\hbar k_x)}{dt} \]

\[ 0 = \frac{dE_C(x)}{dx} v_x + v_x \frac{d(\hbar k_x)}{dt} \]

\[ \frac{d(\hbar k_x)}{dt} = F_e = - \frac{dE_C(x)}{dx} \]
semi-classical transport

\[ \frac{d(\hbar \vec{k})}{dt} = -\nabla_r E_C(\vec{r}) = -q\vec{E}(\vec{r}) \]

\[ \left\{ \begin{aligned} \frac{d\vec{p}}{dt} &= \vec{F}_e \\ \end{aligned} \right. \]

\[ \hbar \vec{k}(t) = \hbar \vec{k}(0) + \int_0^t -q\vec{E}(t')dt' \]

\[ \vec{v}_g(t) = \frac{1}{\hbar} \nabla_k E[\vec{k}(t)] \]

\[ \vec{r}(t) = \vec{r}(0) + \int_0^t \vec{v}_g(t')dt' \]

in-scattering – out-scattering

See Lundstrom: pp. 139-141. The RTA can be justified when the scattering is **isotropic and/or elastic** in which case the proper time to use is the “momentum relaxation time.”
meaning of the RTA

\[
\frac{\partial f}{\partial t} + \vec{v} \bullet \nabla_r f + \vec{F}_e \bullet \nabla_p f = -\frac{\delta f}{\tau_m}
\]

Assume spatial uniformity, no \(E\)-field.

\[
\frac{\partial f}{\partial t} = -\frac{\delta f}{\tau_m}
\]

\[
\delta f = f - f_0
\]

\[
\frac{\partial (\delta f)}{\partial t} = -\frac{\delta f}{\tau_m}
\]

\[
\delta f(t) = \delta f(0) e^{-t/\tau_m}
\]
