Unit 2: Advanced Boolean Algebra

Lecture 2.6: Boolean Difference and Quantification

Anand Raghunathan

raghunathan@purdue.edu

## Outline

- 2.1 Boolean algebra: Quick review
- 2.2 Boolean spaces and functions
- 2.3 Boolean function representations
- 2.4 Conversion of Boolean function representations
- 2.5 Co-factors of Boolean functions
- 2.6 Boolean difference and Quantification

## Combinations of Co-factors

- Combining  $f_x$  and  $f_{x'}$  in different ways leads to useful new functions

$$- f_x \oplus f_{x'} = ?$$

$$- f_x \cdot f_{x'} = ?$$

$$- f_x + f_{x'} = ?$$

## Another analogy to the "Real" world

- The derivative of a function measures how much it changes when it's input changes
- What is the analogy in the case of Boolean functions (which only take values 0 and 1)?
  - Does a function change when it's input changes?

$$f'(x) = \lim_{\Delta \rightarrow 0} \frac{f(x+\Delta) - f(x)}{\Delta}$$

## Boolean Difference

- Boolean difference of a function w.r.t. a variable is the exclusive-OR of the Shannon co-factors w.r.t. the variable
- Interpretation:  $\frac{\partial f}{\partial x} = 1 \rightarrow f$  is sensitive to the value of  $x$
- A new function that does not depend on  $x$

$$\frac{\partial f}{\partial x} = f_x \oplus f_{x'}$$

### Example:

$$f = xy + w'z + x'w'$$

$$f_x = y + w'z$$

$$f_{x'} = w'z + w' = w'$$

$$\frac{\partial f}{\partial x} = (y + w'z) \oplus w'$$

$$= (y + w'z)'w' + (y + w'z)w$$

$$= y'(w+z)w' + wy$$

$$= w'y'z + wy$$

# Boolean Difference

- Examples:

$$S = a \oplus b \oplus c_{in}$$

$$c_{out} = ab + bc_{in} + ac_{in}$$

$$\frac{\partial s}{\partial a} = s_a \oplus s_{a'} = (b \oplus c_{in}) \oplus (b \oplus c_{in}) = 1$$

$$\frac{\partial c_{out}}{\partial c_{in}} = (a+b) \oplus ab$$

$$= (a'b')ab + (a+b)(a'+b')$$

$$= a'b + ab' = a \oplus b$$

$$\text{out} = s'a + sb$$

$$\frac{\partial \text{out}}{\partial a} =$$

$$\frac{\partial \text{out}}{\partial s} = a \oplus b$$

## Application of Boolean Difference

- Manufacturing test
  - Apply test vectors to ensure that each fabricated instance of an IC is functional
  - Cannot apply exhaustive test set (too big!)
- Fault model: Abstraction of physical defects that could impact the IC
  - Most commonly used: “stuck-at” fault model
  - Signals in the circuit are **stuck-at-0**, **stuck-at-1**

How do you derive a test vector to detect the fault c s-a-0?

- Set  $c = 1$
- Set other inputs such that output of good and faulty circuits are different

Looks familiar?

# Quantification

- Two more functions of Shannon cofactors
  - $f_{x_i} \cdot f_{x_i'} = 1$  specifies when  $f = 1$  independent of the value of  $x_i$ 
    - $f(x_1 \dots x_{i-1}, \underline{x_i=1}, x_{i+1} \dots x_n) = 1$  AND
    - $f(x_1 \dots x_{i-1}, \underline{x_i=0}, x_{i+1} \dots x_n) = 1$
  - Called **Universal quantification** or **Consensus**

$$\boxed{\forall x(f) = f_x \cdot f_{x'}}$$
$$\boxed{C_x(f)}$$

# Universal Quantification / Consensus: Geometric Interpretation

Keep vertices where  $f = 1$  independent of  $a$  in the on-set of consensus function

# Universal Quantification / Consensus: Circuit interpretation

# Quantification

- Two more functions of Shannon co-factors
  - $f_{x_i} \cdot f_{x'_i} = 1$  specifies when  $f = 1$  independent of the value of  $x_i$ 
    - $f(x_1 \dots x_{i-1}, \mathbf{x}_i = 1, x_{i+1} \dots x_n) = 1$  AND
    - $f(x_1 \dots x_{i-1}, \mathbf{x}_i = 0, x_{i+1} \dots x_n) = 1$
  - Called **Universal quantification** or **Consensus**
  - $f_x + f_{x'} = 1$  specifies when  $f = 1$  for at least one value of  $x_i$ 
    - $f(x_1 \dots x_{i-1}, \mathbf{x}_i = 1, x_{i+1} \dots x_n) = 1$  OR
    - $f(x_1 \dots x_{i-1}, \mathbf{x}_i = 0, x_{i+1} \dots x_n) = 1$
  - Called **Existential quantification** or **Smoothing**

$$\forall x(f) = f_x \cdot f_{x'}$$

$$C_x(f)$$

$$\exists x(f) = f_x + f_{x'}$$

$$S_x(f)$$

# Existential Quantification / Smoothing: Geometric interpretation

Geometric interpretation: If an off-set vertex has an on-set neighbor in the a-dimension, move it into the on-set

# Existential Quantification / Smoothing: Circuit interpretation

# Boolean Quantification: Examples

$$S = a \oplus b \oplus c$$

$$c_{out} = ab + bc_{in} + ac_{in}$$

$$\forall a(s) = s_a \cdot s_{a'} = (b \oplus c) \cdot (b \oplus c) = 0$$

$$\forall c_{in}(s) = 0$$

$$\exists a(c_{out}) = c_{out}^a + c_{out}^{a'} = b + c_{in} + b c_{in} = b + c_{in}$$

$$\exists c_{in}(c_{out}) =$$

$$\text{out} = s'a + sb$$

$$\forall a(\text{out}) =$$

$$\forall s(\text{out}) = ab$$

$$\exists a(\text{out}) =$$

$$\exists s(\text{out}) = a + b$$

# Properties of Boolean Quantification

- Can be applied w.r.t. multiple variables, order does not matter

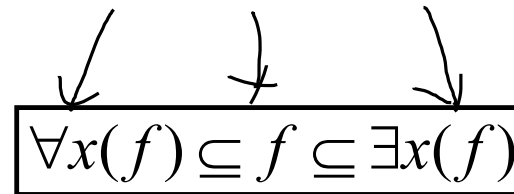

- $C_{xy}(f) = \widehat{C_x(C_y(f))} = \widehat{C_y(C_x(f))}$  ✓

- $S_{xy}(f) = S_x(S_y(f)) = S_y(S_x(f))$  ✓

- Containment properties

- Consensus of a function  $f$  w.r.t. variable  $x$  is contained in  $f$

- Smoothing of a function  $f$  w.r.t. variable  $x$  contains  $f$

$$\boxed{\forall x(f) \subseteq f \subseteq \exists x(f)}$$

$$\boxed{C_x(f) \subseteq f \subseteq S_x(f)}$$

Hint: For containment, think of a function in terms of its on-set ✓

## Unit 2: Summary

- Boolean Algebra: Quick Review
- Advanced Boolean Algebra
  - Boolean spaces and functions
  - Representations of Boolean functions
  - Operations on Boolean functions
  - Co-factors and their applications
    - Shannon's expansion
    - Boolean difference
    - Existential and Universal Quantification

## Reading for Unit 3: Two-level synthesis

- De Micheli, Chapter 7.1-7.4, 7.7
- Hachtel & Somenzi, Chapter 4, Chapter 5

# Acknowledgments

- Prof. Sharad Malik, Princeton
- Prof. Rob Rutenbar, Carnegie Mellon University (now at University of Pittsburgh)
- Prof. Maciej Ciesielski, University of Massachusetts
